Introduction

- Two tools under consideration
- **APC Production system**

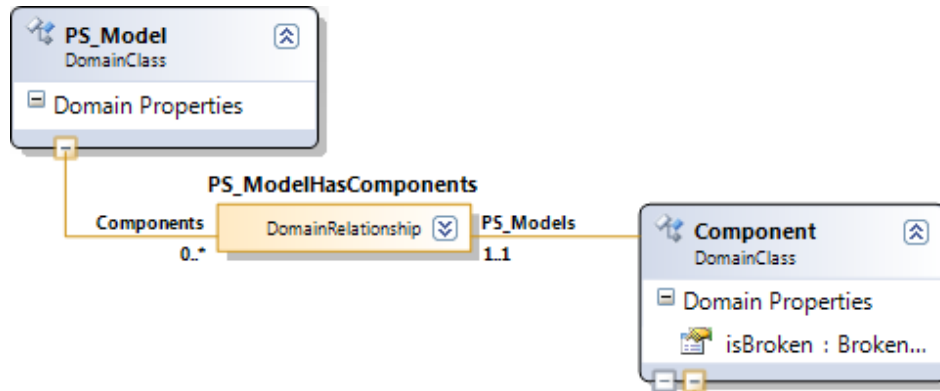

Introduction

- Two tools under consideration
- APC Production system
 - Constraints
 - Machine can have at most one output
 - No self-loops with conveyor belts
 - Generators/Garages
 - Cardinalities

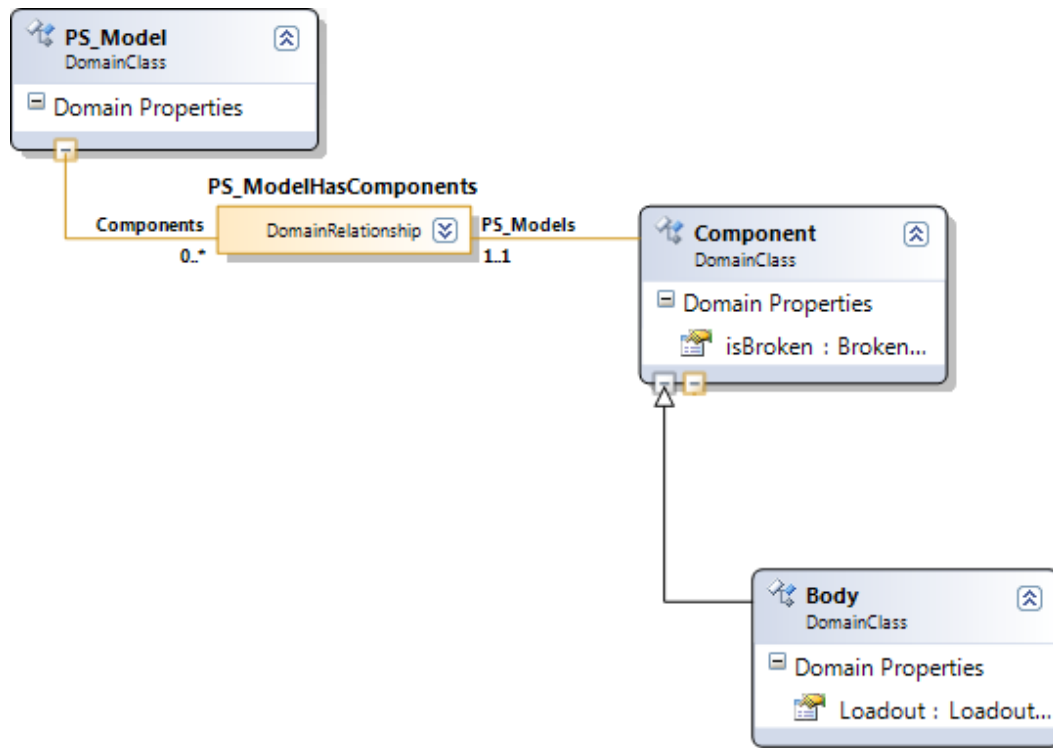

(Meta-)modeling in VM SDK

Validation

- Three types of validation

Validation

- Three types of validation
 - Validation on request

	Description	File
✘ 3	A Quality Control station should have exactly two outgoing links	Validation.pr
✘ 4	A Garage should not have any outgoing links	Validation.pr
✘ 5	A Generator should not have any incoming links	Validation.pr
✘ 6	A Machine (with exception of the Quality Control) should have only 1 outgoing link	Validation.pr

Validation

- Three types of validation
 - Validation on request
 - Interactive constraints

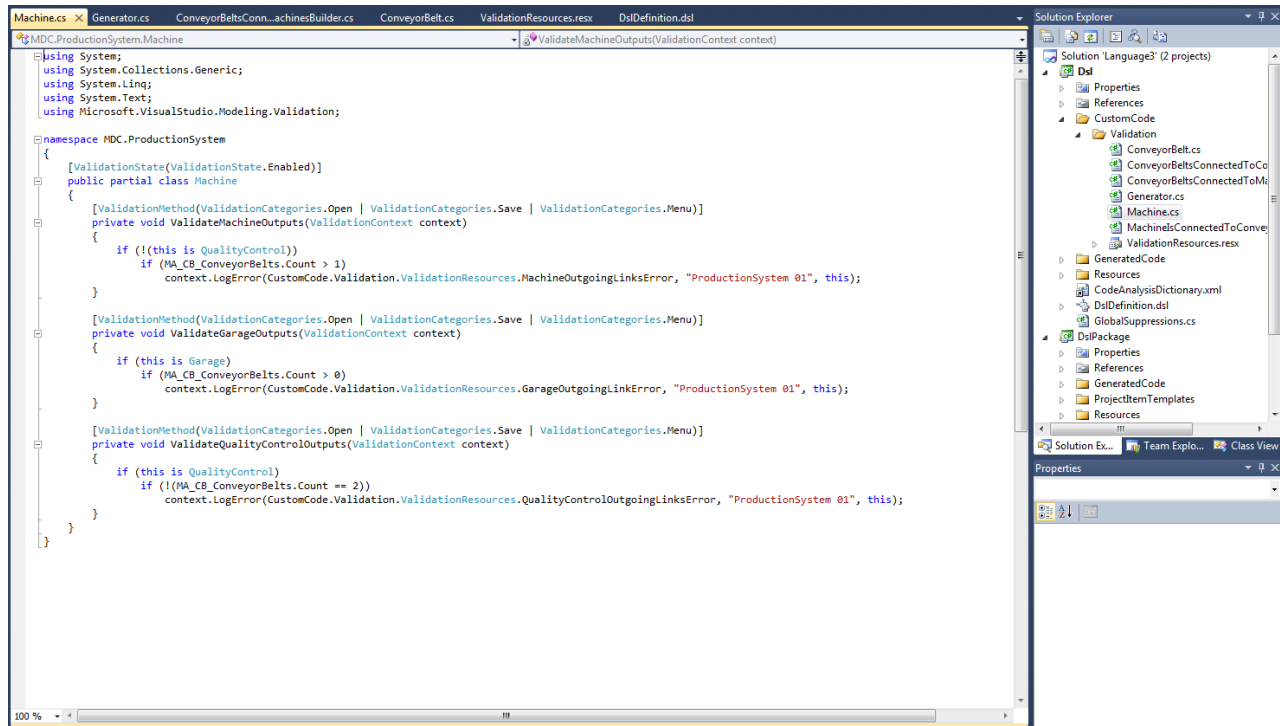

Validation

- **Three types of validation**
 - Validation on request
 - Interactive constraints
 - **Hard constraints**

Validation

- Three types of validation
- Feels like a workaround

```
Machine.cs | Generator.cs | ConveyorBeltsConn...achinesBuilder.cs | ConveyorBelt.cs | ValidationResources.resx | DslDefinition.dsl
MDC.ProductionSystem.Machine | ValidateMachineOutputs(ValidationContext context)
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using Microsoft.VisualStudio.Modeling.Validation;

namespace MDC.ProductionSystem
{
    [ValidationState(ValidationState.Enabled)]
    public partial class Machine
    {
        [ValidationMethod(ValidationCategories.Open | ValidationCategories.Save | ValidationCategories.Menu)]
        private void ValidateMachineOutputs(ValidationContext context)
        {
            if (!(this is QualityControl))
            {
                if (MA_CB_ConveyorBelts.Count > 1)
                    context.LogError(CustomCode.Validation.ValidationResources.MachineOutgoingLinksError, "ProductionSystem 01", this);
            }

            [ValidationMethod(ValidationCategories.Open | ValidationCategories.Save | ValidationCategories.Menu)]
            private void ValidateGarageOutputs(ValidationContext context)
            {
                if (this is Garage)
                {
                    if (MA_CB_ConveyorBelts.Count > 0)
                        context.LogError(CustomCode.Validation.ValidationResources.GarageOutgoingLinkError, "ProductionSystem 01", this);
                }

                [ValidationMethod(ValidationCategories.Open | ValidationCategories.Save | ValidationCategories.Menu)]
                private void ValidateQualityControlOutputs(ValidationContext context)
                {
                    if (this is QualityControl)
                    {
                        if (!(MA_CB_ConveyorBelts.Count == 2))
                            context.LogError(CustomCode.Validation.ValidationResources.QualityControlOutgoingLinksError, "ProductionSystem 01", this);
                    }
                }
            }
        }
    }
}
```

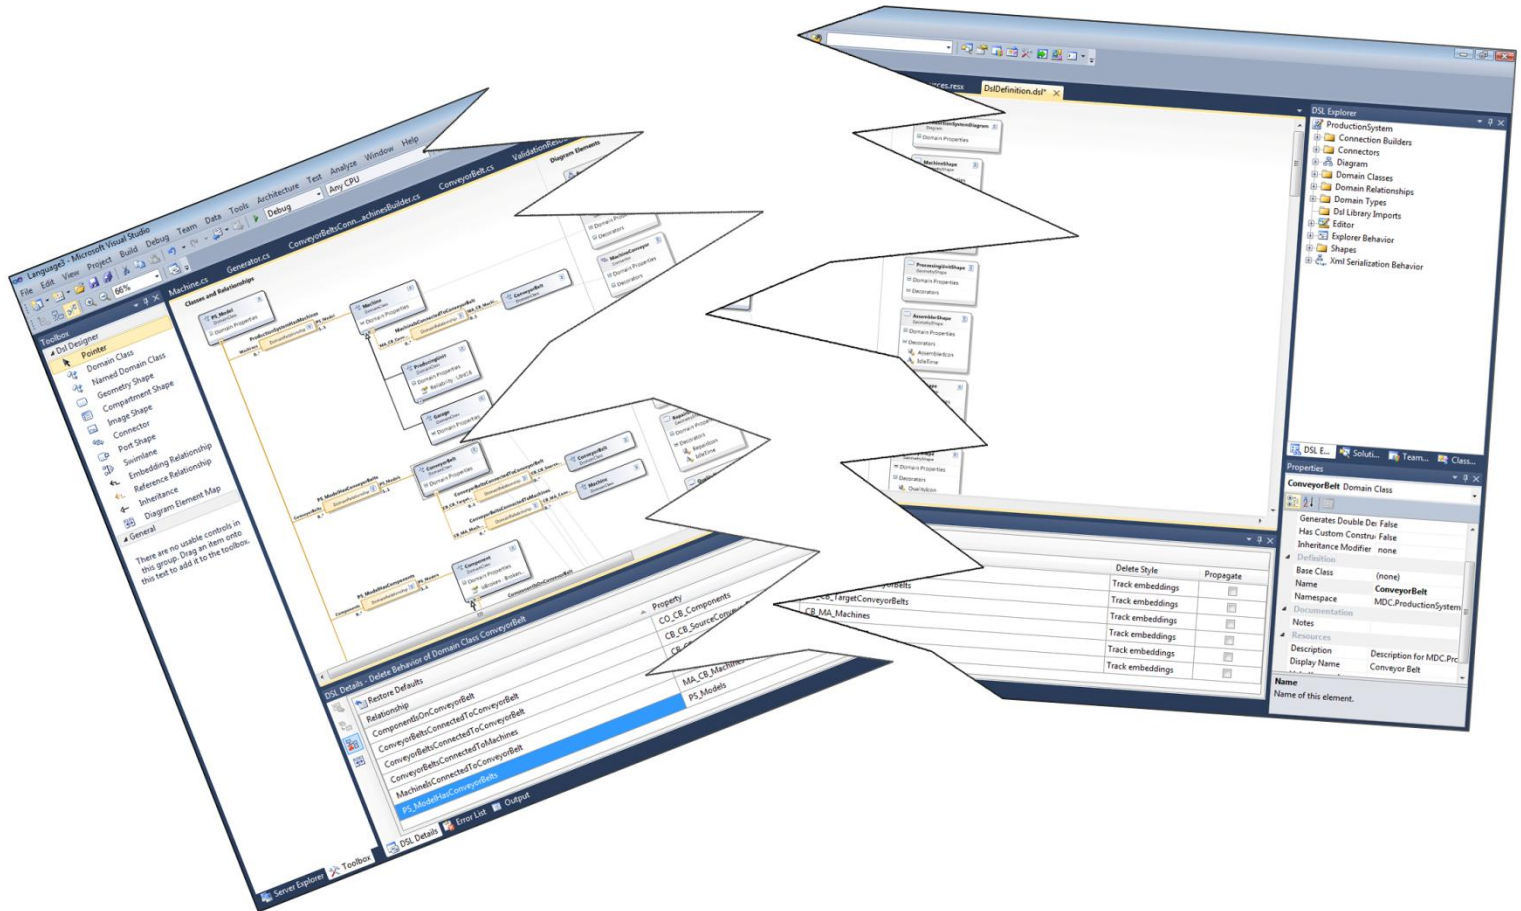

The screenshot shows a Visual Studio IDE with a C# code file open. The code defines a `Machine` class within the `MDC.ProductionSystem` namespace. It includes several validation methods: `ValidateMachineOutputs`, `ValidateGarageOutputs`, and `ValidateQualityControlOutputs`. Each method is decorated with `[ValidationMethod]` attributes. The `ValidateMachineOutputs` method checks for a count of conveyor belts greater than 1. The `ValidateGarageOutputs` method checks for a count greater than 0. The `ValidateQualityControlOutputs` method checks for a count not equal to 2. The code also includes using statements for `System`, `System.Collections.Generic`, `System.Linq`, `System.Text`, and `Microsoft.VisualStudio.Modeling.Validation`. The Solution Explorer on the right shows a project structure with folders for `Validation`, `GeneratedCode`, `Resources`, and `ProjectItemTemplates`.

Validation

- Three types of validation
- Feels like a workaround

Simulation

Simulation – T4 Text Templates

```
<#@ template inherits="Microsoft.VisualStudio.TextTemplating.VSHost.ModelingTextTransformation" #>
<#@ output extension=".txt" #>
<#@ ProductionSystem processor="ProductionSystemDirectiveProcessor" requires="fileName='MachinesCantFire.pr'" #>
```

```
=====
Analysis of the file MachinesCantFire.pr
=====
```

The following is a list of all the machines currently operated by operators also indicating if they are able to function or if there is an obstruction.

```
<#
// When you change the DSL Definition, some of the code below may not work.
```

```
foreach (Operator op in this.PS_Model.Operators)
{
    if (op.OP_PU_ProcessingUnits != null)
    {
        Machine mach = op.OP_PU_ProcessingUnits;
        if (mach is RepairBay)
        {
            bool hasInput = false;
            bool canOutput = false;
            foreach (ConveyorBelt conv in mach.CB_MA_ConveyorBelts)
            {
                if (conv.CO_CB_Components != null)
                {
                    hasInput = true;
                }
            }
            foreach (ConveyorBelt conv in mach.MA_CB_ConveyorBelts)
            {
                if (conv.CO_CB_Components == null)
                {
                    canOutput = true;
                }
            }
            if (hasInput)
            {
                if (canOutput)
```

=====

The following is a list of all the machines currently operated by operators
also indicating if they are able to function or if there is an obstruction.

The assembler operated by Amy is NOT ready to produce,
it requires additional components to begin production.

The repair bay currently operated by Bruno is NOT ready to repair the supplied component,
either there is no conveyor belt leading out of this machine or there is already another item on it.

Comparison

- Strong points of VM SDK
 - Ease-of-use from a programmer's POV

Comparison

- Strong points of VMSDK
 - Ease-of-use from a programmer's POV
 - Everything under the same roof

Comparison

- Strong points of VMSDK
 - Ease-of-use from a programmer's POV
 - Everything under the same roof
 - Easy design of graphical object

Comparison
