Questions

Motivation

- ▶ Software product line engineering (SPLE)
- ▶ High up-front investment
- ▶ Proactive, reactive and extractive SPLE

Motivation

- ▶ Software product line engineering (SPLE)
- ▶ High up-front investment
- ▶ Proactive, reactive and extractive SPLE

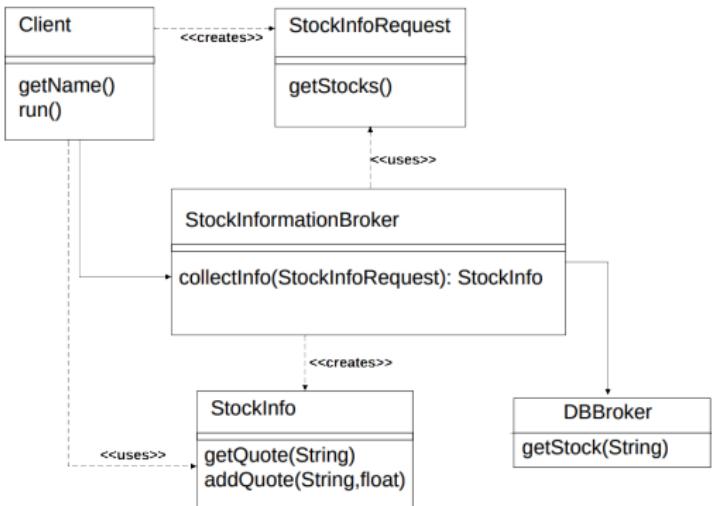

Need for

- ▶ Tool support
- ▶ Techniques for domain implementation

Related Work Example

```
class Client {  
    String getName(){...}  
    void run(){...}  
}  
class StockInformationBroker {  
    StockInfo collectInfo(  
        StockInfoRequest r){...}  
}  
class DBBroker {  
    Stock getStock() { ... }  
}  
class StockInfoRequest {  
    StockInfo getStocks(){...}  
}
```

Add pricing functionality

Example

```
class Client {  
    String getName(){...}  
    void run(){...}  
    float balance;  
    float balance() { return balance; }  
    void charge(StockInfoRequest r) { balance -= r.price(); }  
}  
class StockInformationBroker {  
    StockInfo collectInfo(Client c, StockInfoRequest r){  
        ...  
        c.charge(r);  
    }  
}  
class DBBroker {  
    Stock getStock() { ... }  
}  
class StockInfoRequest {  
    StockInfo getStocks(){...}  
    float price() { return basicPrice() + calculateTax(); }  
    float basicPrice() { return 5 + getStocks().length*0.2; }  
    float calculateTax() { ... }  
}
```

Example Preprocessor Directives

```
class Client {
    String getName(){...}
    void run(){...}
#ifndef PRICING
    float balance;
    float balance() { return balance; }
    void charge(StockInfoRequest r) { balance -= r.price(); }
#endif
}
class StockInformationBroker {
    StockInfo collectInfo(Client c, StockInfoRequest r){
        ...
#ifndef PRICING
        c.charge(r);
#endif
    }
}
class DBBroker {
    Stock getStock() {...}
}
...
```

Example Architecture: Mixins

```
class Client {  
    String getName(){...}  
    void run(){...}  
}  
  
template <class Super>  
class Pricing: public Super{  
    float balance;  
    float balance() { return balance; }  
    void charge(StockInfoRequest r) { balance -= r.price(); }  
};  
  
typedef Pricing<Client>ClientPricing;  
...
```

Example

Aspect-oriented Programming

```
aspect Pricing {
    private float Client.balance;
    float Client.balance() { return balance; }
    void Client.charge(StockInfoRequest r) {
        balance -= r.price();
    }
    float StockInfoRequest.price() { ... }
    after( Client c, StockInfoRequest request ):
        (call (StockInfo collectInfo(StockInfoRequest))
        && this(c) && args(request)) {
            c.charge(request);
    }
}
```

Example

Feature-oriented Programming (AHEAD)

```
refines class Client {
    float balance;
    public float balance() { return balance; }
    void charge(StockInfoRequest r) { balance -= r.price(); }
}
refines class StockInfoRequest {
    float price() { return basicPrice() + calculateTax(); }
    float basicPrice() { return 5 + getStocks().length*0.2; }
    float calculateTax() { ... }
}
refines class StockInformationBroker {
    StockInfo collectInfo(Client c, StockInfoRequest r) {
        super.collectInfo(c, r);
        c.charge(r);
    }
}
```

Example

Delta-oriented Programming

```
delta DClient{
    modifies class Client {
        adds float balance;
        adds float balance() { return balance; }
        adds void charge(StockInfoRequest r) { balance -= r.price(); }
    }
    modifies class StockInformationBroker {
        adds StockInfo collectInfo()( Client c, StockInfoRequest r) {
            collectInfo(r);
            c.charge(r);
        }
    }
}
```

Example Tool Support

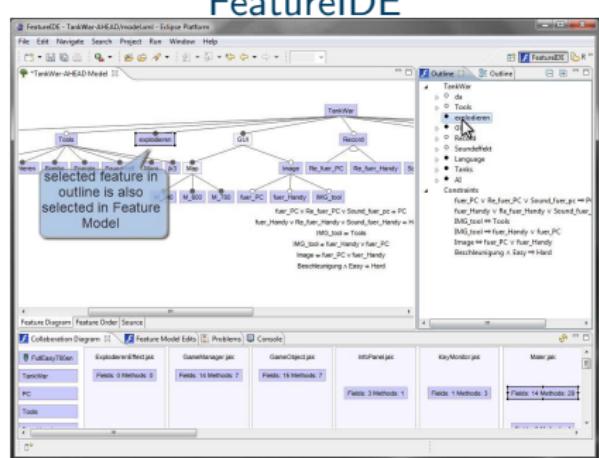

CIDE

The screenshot shows the CIDE IDE interface. On the left, a Notepad.java file contains Java code for a game engine. The code includes logic for handling user input, applying user advice, and updating game states. On the right, an AST View window displays the Abstract Syntax Tree (AST) corresponding to the code in Notepad.java.

```
Notepad.java
public void actionPerformed(ActionEvent e) {
    public void actionPerformed(ActionEvent e) {
        if (user.isSelected()) {
            t = t.applyUser("u" + layerno);
        }
        if (advise.isSelected()) {
            t = t.applyUser advice("a" + layerno);
        }
        if (intro.isSelected()) {
            t = t.applyUser intro("i" + layerno);
        }
        if (graphic.isSelected()) {
            t = t.applyUser graphic("g" + layerno);
        }
        if (beam.isSelected() || advance.isSelected() || intro.isSelected() || beam.isSelected(false)) {
            beam.setSelected(false);
            layerno++;
            intro.setSelected(false);
            equation.setText("F" + layerno + "!" + equation.get());
        }
    }
}
```

AST View:

 - IF (444, 813)

Layered Programming

- ▶ Delta-oriented programming
- ▶ Only tool based
 - ▶ diff-match-patch
 - ▶ Feature model
 - ▶ CLI like git
 - ▶ Editor

Layered Programming Demo

Layered Programming Benefits

- ▶ System has multiple representations → keep them consistent
- ▶ Language independent
- ▶ Easy to use
 - ▶ No new language or complex structure
 - ▶ Semantically clear (WYSIWYG)
 - ▶ Features added where they are used
 - ▶ No intermediary representation
- ▶ Robust (to be verified)
- ▶ Proactive, reactive and extractive SPLE

Layered Programming Risks

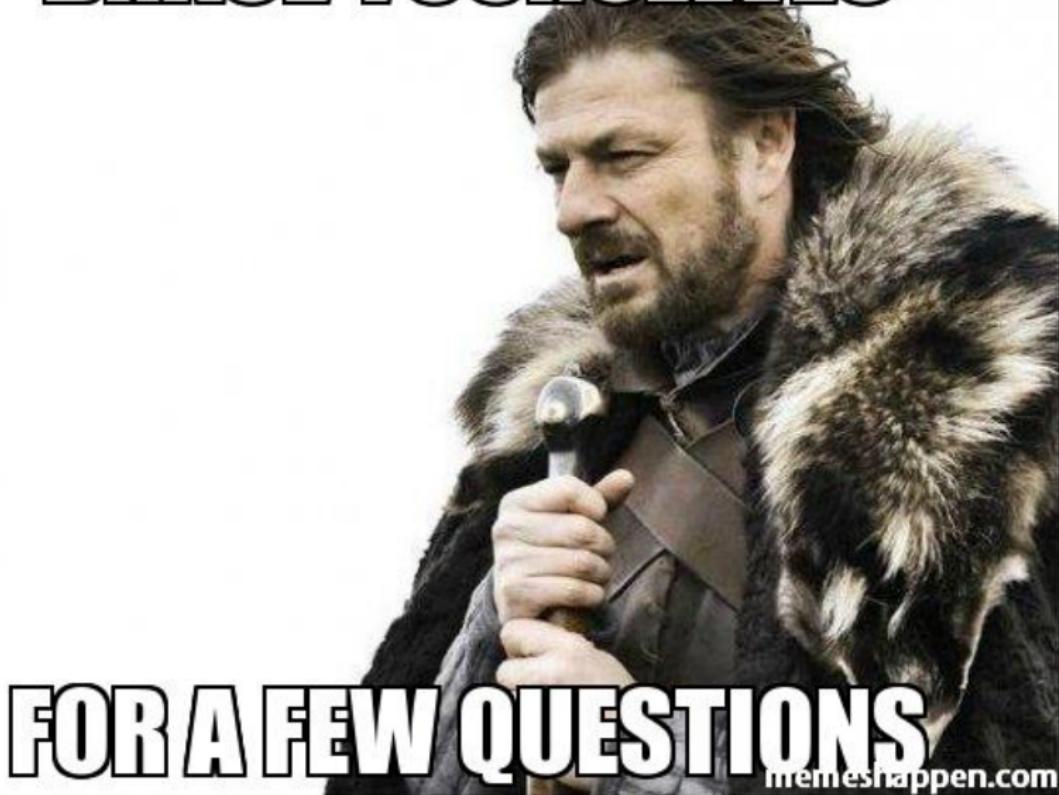

- ▶ Interaction with version management (git)
- ▶ Is it robust under changes to base
- ▶ Can conflicting features be detected?
- ▶ What should happen with conflicting features?
- ▶ How to deal with optional layer interactions?

Planning

- ▶ Analyze risks and propose solutions/workarounds
- ▶ Algorithm and tool to support layered programming
- ▶ Encoding for layers
- ▶ Feature model support
