artifacts are generated from domain-specific models (dsms)

artifacts may be configuration files, programs, performance models, etc.

rules of the trade dictate that artifact generation should be done via ${\color{black} model}$ transformations

the typical steps of a dsm project are...

- **1** modelling a domain-specific language (dsl)
- **2** specifying its semantics as model transformations
- 3 creating instance dsms
- 4 synthesizing artifacts from dsms

debugging	in dsm 101			

the development process in dsm has two important facets: developing models and developing model transformations

this introduces two important differences with the programming world:

- **1** artifacts to debug are not restricted to code
- 2 designing and debugging "Compilers/interpreters" is now common

in the paper, we explore how all of the above language and debugging facilities translate into the debugging stages of both facets of dsm development

in this talk, we focus only on print statements, exceptions and execution control

we focus only on rule-based model transformations

a rule-based model transformation describes a flow of $rules^{\ast}$ (which may require debugging)

we should remember that print statements (whose usefulness is mostly restricted to debugging purposes) are supported in every modern GPL

which exceptions to catch and propagate are design decisions of the dsl architect

- "silent" handlers for irrelevant exceptions should be generated alongside synthesized artifacts
- relevant exceptions should be translated into domain-specific terms and propagated to the modeller or designer

stepping, models and artifacts...

generating artifacts from ds*m*s creates an **implicit hierarchy** between them

a designer may prefer for the step into operation to take a step at the level of corresponding lower level entities*

context and problem debugging: code vs. dsm debugging transformations 000000 00000 00000	debugging models and artifacts 00000●	conclusion 000

pausing, models and artifacts...

a sensible approach is to pause the execution before running...

- the next step at the ds*m* level for the modeller
- the next step at the artifact level for the designer

a key enabler for pausing and stepping is (ideally automatic) instrumentation of artifacts to enable running only parts of them at a time
